- A `wildcard` query uses `*` and `?` operators to fetch results.
- Fuzziness employs Levenshtein's edit distance to fetch similar-looking words. Elasticsearch employs `fuzzy` queries to support the user's spelling inconsistencies.
- A `prefix` query retrieves results given a prefix (no need to specify a wildcard operator). As prefix operations are expensive to execute on a live index, we can ask Elasticsearch to pre-create them at index time to avoid finding them during a live query phase.
