```
      "fields": ["title","synopsis"]
    }
  },
  "highlight": {
    "fields": {
      "tags": {},
      "title": {}
    }
  }
}
```

Suppresses the source but shows the highlights

We query for "Design Patterns" across the `title` and `synopsis` fields. This time, we explicitly instruct the `multi_match` query to use the `best_fields` type.

> **NOTE** The default type for a `multi_match` query is `best_fields`. The `best_fields` algorithm ranks the field with the most words higher than that with the fewest.

If you look at the response and the scores (see the following code snippet), you'll see that the book *Head First Design Patterns* has a score of 6.9938974 compared to *Head First Object-Oriented Analysis Design*, which has a score of 2.9220228:

```
"hits" : [{
  "_index" : "books",
  "_id" : "10",
  "_score" : 6.9938974,
  "highlight" : {
    "title" : [
      "Head First <em>Design</em> <em>Patterns</em>"
    ]
  }
},
{
  "_index" : "books",
  "_id" : "8",
  "_score" : 2.9220228,
  "highlight" : {
    "title" : [
      "Head First Object-Oriented Analysis <em>Design</em>"
    ]
  }
}
...]
```

There are other types of `multi-match` queries, including `cross_fields`, `most_fields`, `phrase`, and `phrase_prefix`. We can use the `type` parameter to set the query type to search for the best match among multiple fields. However, we won't delve into all these types here; consult Elasticsearch's documentation for more information.

How does Elasticsearch carry out a `multi_match` query? It is rewritten using a disjunction max (`dis_max`) query behind the scenes. We discuss this query type next.
