```
        "field": "user_ratings",
        "factor": 2,
        "modifier": "square"
      }
    }
  }
}
```

This script fetches the value of `user_ratings` from the document. It then multiplies the value by a factor of 2 and squares it.

11.7.4 Combining function scores

We looked at individual functions in the last few sections, but we can also combine functions to produce an even better score. For example, the following listing shows a `function_score` query that produces a score employing two functions: `weight` and `field_value_factor`.

Listing 11.31 Two functions producing a unified score

```
GET products/_search
{
  "query": {
    "function_score": {
      "query": {
        "term": {
          "product": "TV"
        }
      },
      "functions": [
        {
          "filter": {
            "term": {
              "brand": "LG"
            }
          },
          "weight": 3
        },
        {
          "filter": {
            "range": {
              "user_ratings": {
                "gte": 4.5,
                "lte": 5
              }
            }
          },
          "field_value_factor": {
            "field": "user_ratings",
            "factor": 5,
            "modifier": "square"
          }
        }
```

The functions object, which expects an array of leaf functions

The weight function

The field_value_factor is based on the user_ratings field.
